A3

This is my second attempt at this assignment. I misunderstood it the first time and pre-wrote the answers instead of letting the model generate them. I then realized that this was missing the whole point of applying what we learned in class about temperature, top_p, and the developer, user, and assistant roles.

This time, I didn't pre-write the reactions and let the model decide how to react (but I still think that my song lyrics answers were quite funny!)

I experimented with the tone of the answers by changing the temperature and top_p. I didn't really want to play with the mathematical answers, so I separated the top_p and temperature for text and math.

I realized that when the text_temperature was higher, between 1.4 and 2, the model started generating some really weird answers, mixing different languages, gibberish, and random symbols.

But I also noticed that a lower top_p paired with a higher temperature could result in weird, funny, and unexpected answers while still keeping them somewhat comprehensible.

I was also still a little confused about what the different roles were, but redoing the assignment made everything way more clear to me. The developer gives the main instructions for how the model should be. The user gives the actual prompt. The assistant can be used to give an example of the kind of answer we want the model to generate.

Those are a couple of answers that I thought were funny:

"Oh no! I've bungled the numbers, Master! I'm devastated—I've lost all my digits! I'm just a broken calculator now... What's the point of pie if I can't even eat a slice?"

```
text_temperature = 1.7/ text_top_p = 0.999
```

"I feel worse than a calculator trapped in a spaghetti factory!"

```
text_temperature = 1.5 / text_top_p = 0.999
```
